(54) Title: CACNA1G POLYNUCLEOTIDE, POLYPEPTIDE AND METHODS OF USE THEREFOR

(57) Abstract: A novel T-type calcium channel (CACNA1G) is provided, as are polynucleotides encoding the same. CACNA1G has been implicated in cellular proliferative disorders. More specifically, it has been observed that the methylation state of specific regions within CpG islands associated with the CACNA1G gene correlates with a number of cancerous phenotypes involving a variety of tissue and cell types. Also provided are methods for detecting cellular proliferative disorders by determining the methylation state of genes or regulatory regions associated therewith, including CACNA1G, as well as kits containing reagents for performing invention methods.

WO 01/019845 A1

CACNA1G POLYNUCLEOTIDE , POLYPEPTIDE and METHODS OF USE THEREFOR

STATEMENT AS TO FEDERALLY SPONSORED RESEARCH

5

This invention was made with Government support under Grant No. CA43318 and CA54396, awarded by the National Cancer Institute and Grant No. CA43318, a Colon Cancer Spore Grant. The government may have certain rights in the invention.

10

FIELD OF THE INVENTION

The present invention relates generally to the regulation of gene expression and more specifically to a method of determining the DNA methylation status of CpG sites in a given locus and correlating the methylation status with the presence of a cell proliferative disorder.

15

BACKGROUND OF THE INVENTION

DNA methylases transfer methyl groups from the universal methyl donor S-adenosyl methionine to specific sites on the DNA. Several biological functions have been attributed to the methylated bases in DNA. The most established biological function for methylated DNA is the protection of DNA from digestion by cognate restriction enzymes. The restriction modification phenomenon has, so far, been observed only in bacteria. Mammalian cells, however, possess a different methylase that exclusively methylates cytosine residues that are 5' neighbors of guanine (CpG). This modification of cytosine residues has important regulatory effects on gene expression, especially when involving CpG rich areas, known as CpG islands, located in the promoter regions of many genes.

20

25

30

Methylation has been shown by several lines of evidence to play a role in gene activity, cell differentiation, tumorigenesis, X-chromosome inactivation, genomic imprinting and other major biological processes (Razin, A., H., and Riggs, R.D. eds.

in DNA Methylation Biochemistry and Biological Significance, Springer-Verlag, New York, 1984). In eukaryotic cells, methylation of cytosine residues that are immediately 5' to a guanosine, occurs predominantly in CG poor regions (Bird, A., Nature, 321:209, 1986). In contrast, CpG islands remain unmethylated in normal
5 cells, except during X-chromosome inactivation (Migeon, et al., supra) and parental specific imprinting (Li, et al., Nature, 366:362, 1993) where methylation of 5' regulatory regions can lead to transcriptional repression. De novo methylation of the Rb gene has been demonstrated in a small fraction of retinoblastomas (Sakai, et al., Am. J. Hum. Genet., 48:880, 1991), and recently, a more detailed analysis of the VHL
10 gene showed aberrant methylation in a subset of sporadic renal cell carcinomas (Herman, et al., Proc. Natl. Acad. Sci., U.S.A., 91:9700, 1994). Expression of a tumor suppressor gene can also be abolished by de novo DNA methylation of a normally unmethylated CpG island (Issa, et al., Nature Genet., 7:536, 1994; Herman, et al., supra; Merlo, et al., Nature Med., 1:686, 1995; Herman, et al., Cancer Res., 56:722,
15 1996; Graff, et al., Cancer Res., 55:5195, 1995; Herman, et al., Cancer Res., 55:4525, 1995).

Human cancer cells typically contain somatically altered nucleic acid, characterized by mutation, amplification, or deletion of critical genes. In addition,
20 the nucleic acid from human cancer cells often displays somatic changes in DNA methylation (E.R. Fearon, et al., Cell, 61:759, 1990; P.A. Jones, et al., Cancer Res., 46:461, 1986; R. Holliday, Science, 238:163, 1987; A. De Bustros, et al., Proc. Natl. Acad. Sci., USA, 85:5693, 1988); P.A. Jones, et al., Adv. Cancer Res., 54:1, 1990; S.B. Baylin, et al., Cancer Cells, 3:383, 1991; M. Makos, et al., Proc. Natl. Acad. Sci.,
25 USA, 89:1929, 1992; N. Ohtani-Fujita, et al., Onco-gene, 8:1063, 1993). However, the precise role of abnormal DNA methylation in human tumorigenesis has not been established.

Aberrant methylation of normally unmethylated CpG islands has been described as a frequent event in immortalized and transformed cells, and has been
30 associated with transcriptional inactivation of defined tumor suppressor genes in

human cancers. In the development of colorectal cancers (CRC), a series of tumor suppressor genes (TSG) such as APC, p53, DCC and DPC4 are inactivated by mutations and chromosomal deletions (reviewed in Kinzler and Vogelstein 1996). Some of these alterations result from a chromosomal instability phenotype described in a subset of CRC (Lengauer et al., 1997a). Recently, an additional pathway has been shown to be involved in a familial form of CRC, hereditary non-polyposis colorectal cancer. The cancers from these patients show a characteristic mutator phenotype which causes microsatellite instability (MI), and mutations at other gene loci such as TGF-beta-RII (Markowitz et al., 1995) and BAX (Rampino et al., 1997). This phenotype usually results from mutations in the mismatch repair (MMR) genes hMSH2 and hMLH1 (reviewed by Peltomaki, and de la Chapelle, 1997). A subset of sporadic CRC also show MI, but mutations in MMR genes appear to be less frequent in these tumors (Liu et al., 1995; Moslein et al., 1996).

Another molecular defect described in CRC is CpG island (CGI) methylation. CGIs are short sequences rich in the CpG dinucleotide and can be found in the 5' region of about half of all human genes. Methylation of cytosine within 5' CGIs is associated with loss of gene expression and has been seen in physiological conditions such as X chromosome inactivation and genomic imprinting (reviewed in Latham, 1996). Aberrant methylation of CGIs has been detected in genetic diseases such as the fragile-X syndrome, in aging cells and in neoplasia. About half of the tumor suppressor genes which have been shown to be mutated in the germline of patients with familial cancer syndromes have also been shown to be aberrantly methylated in some proportion of sporadic cancers, including Rb, VHL, p16, hMLH1, and BRCA1 (reviewed in Baylin, S.B., Herman, J.G., Graff, J.R., Vertino, P.M. and Issa, J.P. Alterations in DNA methylation: a fundamental aspect of neoplasia, *Adv. Cancer Res.* 72:141-196 1998). TSG methylation in cancer is usually associated with (1) lack of gene transcription and (2) absence of coding region mutation. Thus it has been proposed that CGI methylation serves as an alternative mechanism of gene inactivation in cancer.

The causes and global patterns of CGI methylation in human cancers remain poorly defined. Aging could play a factor in this process because methylation of several CGIs could be detected in an age-related manner in normal colon mucosa as well as in CRC (Issa, J.P., Vertino, P.M., Boehm, C.D., Newsham, I.F. and Baylin, S.B. Methylation of the oestrogen receptor CpG island links ageing and neoplasia in human colon. *Nat Genet.* 7:536-540, 1994). In addition, aberrant methylation of CGIs has been associated with the MI phenotype in CRC as well as specific carcinogen exposures (Issa et al., 1996) supra. However, an understanding of aberrant methylation in CRC has been somewhat limited by the small number of CGIs analyzed to date. In fact, previous studies have suggested that large numbers of CGIs are methylated in immortalized cell lines (Antequera, F., Boyes, J. and Bird, A. High levels of de novo methylation and altered chromatin structure at CpG islands in cell lines. *Cell* 62:503-514, 1990), and it is not well understood whether this global aberrant methylation is caused by the cell culture conditions or whether they are an integral part of the pathogenesis of cancer.

Most of the methods developed to date for detection of methylated cytosine depend upon cleavage of the phosphodiester bond alongside cytosine residues, using either methylation-sensitive restriction enzymes or reactive chemicals such as hydrazine which differentiate between cytosine and its 5-methyl derivative. Genomic sequencing protocols which identify a 5-MeC residue in genomic DNA as a site that is not cleaved by any of the Maxam Gilbert sequencing reactions have also been used, but still suffer disadvantages such as the requirement for large amount of genomic DNA and the difficulty in detecting a gap in a sequencing ladder which may contain bands of varying intensity.

Mapping of methylated regions in DNA has relied primarily on Southern hybridization approaches, based on the inability of methylation-sensitive restriction enzymes to cleave sequences which contain one or more methylated CpG sites. This method provides an assessment of the overall methylation status of CpG islands,

including some quantitative analysis, but is relatively insensitive and requires large amounts of high molecular weight DNA.

Another method utilizes bisulfite treatment of DNA to convert all unmethylated cytosines to uracil. The altered DNA is amplified and sequenced to show the methylation status of all CpG sites. However, this method is technically difficult, labor intensive and without cloning amplified products, it is less sensitive than Southern analysis, requiring approximately 10% of the alleles to be methylated for detection.

Identification of the earliest genetic changes in tumorigenesis is a major focus in molecular cancer research. Diagnostic approaches based on identification of these changes are likely to allow implementation of early detection strategies and novel therapeutic approaches targeting these early changes might lead to more effective cancer treatment.

SUMMARY OF THE INVENTION

The present invention is based on the finding that several genes are newly identified as being differentially methylated in cancer. This seminal discovery is useful for cancer screening, risk-assessment, prognosis, minimal-residual disease identification, staging and identification of therapeutic targets. The identification of new genes that are methylated in cancer, aging or diseases associated with aging increases the likelihood of finding genes methylated in a particular cancer; increases the sensitivity and specificity of methylation detection; allows methylation profiling using multiple genes; and allows identification of new targets for therapeutic intervention. The invention also provides a newly identified gene that is a target for hypermethylation in human tumors. This new gene, as well as genes newly identified as hypermethylated in cancer and aging or aging diseases provides markers which can

be used diagnostically, prognostically and therapeutically over the course of such disorders.

In a first embodiment, the invention provides a nucleic acid molecule
5 comprising a coding region for a T-type calcium channel, CACNA1G, and regulatory
sequences associated therewith. The discovery of CpG islands, and in particular,
methylated CpG islands in the region approximately 300-800 base pairs upstream
from the CACNA1G translation initiation start site, led to a method of the present
invention for correlating methylated CpG islands with various cancers. In one aspect
10 of this embodiment, the nucleic acid molecule encoding CACNA1G and the
associated regulatory sequences and CpG-rich regions include the nucleic acid
sequence set forth in SEQ ID NO:51 (Figure 3A). Also provided is a polypeptide
having an amino acid sequence as set forth in SEQ ID NO:52 and Figure 3B. The
methylation state of CpG islands in CACNA1G, associated regulatory regions, and
15 other genes is indicative of the presence of a cellular proliferative disorder in a subject
from which the CpG-containing nucleic acid is isolated.

In another embodiment, there are provided methods for detecting a cellular
proliferative disorder in a subject. The subject may have or be at risk of having a
20 cellular proliferative disorder. The method of the invention is useful for diagnostic as
well as prognostic analyses. One method for detecting a cellular proliferative disorder
in a subject includes contacting a nucleic acid-containing specimen from the subject
with an agent that provides a determination of the methylation state of at least one
gene or associated regulatory region of the gene; and identifying aberrant methylation
25 of regions of the gene or regulatory region, wherein aberrant methylation is identified
as being different when compared to the same regions of the gene or associated
regulatory region in a subject not having the cellular proliferative, thereby detecting a
cellular proliferative disorder in the subject. The method includes multiplexing by
utilizing a combination of primers for more than one loci, thereby providing a
30 methylation "profile" for more than one gene or regulatory region.

For the first time, the invention provides methylated forms of the following genes and/or their associated regulatory sequences: APOB, CACNA1G, CDX2, EGFR, FBN1, GPR37, HSPA6, IQGAP2, KL, PAR2, PITX2, PTCH, SDC1, and SDC4 (see Table 5). In addition, the invention provides the CpG-rich regions from these genes that are hypermethylated (see Figures 4A-4F (SEQ ID NO:105-119).

Invention methods include determining, in a nucleic acid-containing specimen taken from a subject, the methylation state of a gene or regulatory sequences associated therewith, wherein the expression or non-expression of the gene is associated with the presence of the cellular proliferative disorder, and identifying as having a cellular proliferative disorder a subject that has aberrant methylation of regions of the gene or associated regulatory sequences when compared to the same regions of the gene in a subject not having the cellular proliferative disorder. In one aspect of this embodiment, the methylated regions of the gene and associated regulatory sequences are contained within CpG islands (i.e., CpG rich regions). In particular, the aberrant methylation typically includes hypermethylation as compared with the same regions of the gene or regulatory sequences in a subject not having the cellular proliferative disorder.

Determining the methylation state of the gene includes contacting the nucleic acid-containing specimen with an agent that modifies unmethylated cytosine, amplifying a CpG-containing nucleic acid in the specimen by means of CpG-specific oligonucleotide primers, wherein the oligonucleotide primers distinguish between modified methylated and nonmethylated nucleic acid, and detecting the methylated nucleic acid based on the presence or absence of amplification products produced in said amplifying step. The method includes optionally contacting the amplification products with a methylation sensitive restriction endonuclease. Other methods for determining methylation status of a gene and/or regulatory sequences are well known in the art and are described more fully herein.

In another embodiment, the present invention provides a method of treating a cell proliferative disorder associated with CACNA1G or other methylated genes described herein, comprising administering to a subject with the disorder, a therapeutically effective amount of reagent which modulates CACNA1G or other methylated genes' expression. For example, since CACNA1G -associated disorders typically involve hypermethylation of CACNA1G polynucleotide sequence, a polynucleotide sequence which contains a non-methylatable nucleotide analog is utilized for treatment of a subject. Further, the invention provides a method of gene therapy comprising introducing into cells of a host subject, an expression vector comprising a nucleotide sequence encoding CACNA1G or other methylated genes described herein, in operable linkage with a promoter.

In another embodiment of the present invention there is provided a kit useful for the detection of a cellular proliferative disorder in a subject having or at risk for having a cellular proliferative disorder. Invention kits include a carrier means compartmentalized to receive a sample, one or more containers comprising a first container containing a reagent which modifies unmethylated cytosine and a second container containing primers for amplification of a CpG-containing nucleic acid, wherein the primers distinguish between modified methylated and nonmethylated nucleic acid, and optionally, a third container containing a methylation sensitive restriction endonuclease.

BRIEF DESCRIPTION OF THE FIGURES

Figure 1A shows the relative positions of MINT31 and CACNA1G and associated CpG regions.

5 Figure 1B provides a magnified depiction of MINT31, CACNA1G and CpG rich regions 1-8.

Figure 2 depicts the correlation of methylation and the expression of CACNA1G.

10 Figures 3A and 3B show the nucleic acid sequence and deduced amino acid sequence of CACNA1G (SEQ ID NO:51 and 52, respectively).

Figures 4A-4F show the CpG-rich regions of the genes depicted in Table 5 (SEQ ID NO:105-119).

Figure 5 is the nucleotide sequence of MINT31. (SEQ ID NO:120).

15

DETAILED DESCRIPTION OF THE INVENTION

It has been determined that an aberrant methylation state of nucleic acids in certain genes, particularly regulatory sequences, is diagnostic for the presence or potential development of a cellular proliferative disorder in subjects bearing the aberrantly methylated nucleic acids. More particularly, the hypermethylation of 20 certain nucleotides localized in CpG islands has been shown to affect the expression of genes associated with the CpG islands; typically such hypermethylated genes have reduced or abolished expression, primarily due to down-regulated transcription. Using a recently developed PCR-based technique called methylated CpG island 25 amplification (MCA), several nucleic acid molecules aberrantly methylated in a colon cancer cell line were identified. One DNA fragment, termed MINT31, mapped to human chromosome 17q21 where frequent loss of heterozygosity (LOH) has been detected in various human tumors. By characterizing the genomic sequence around this area, a gene encoding a T-type calcium channel, CACNA1G, was identified as a 30 target for hypermethylation in human tumors. Using RT-PCR, expression of CACNA1G was detected in normal colon and bone marrow, but expression was

absent in 5 tumor cell lines where methylation was found. After treatment with the methylation inhibitor 5-deoxy-azacytidine, the expression of CACNA1G was restored in all 5 cell lines. Detailed methylation mapping of the 5'CpG island by bisulfite-PCR revealed that methylation of a region 300 to 800 base pairs upstream of the translation initiation site closely correlated with the inactivation of CACNA1G. Aberrant methylation of CACNA1G was also examined in various human primary tumors, and was detected in 17 of 49 (35%) colorectal cancers, 4 of 16 (25%) gastric cancers, and 3 of 23 (13%) acute myelogenous leukemia cases. While not wanting to be bound by a particular theory, it is believed that inactivation of CACNA1G may play a role in cancer development by modulating calcium signaling, which potentially affects cell proliferation and apoptosis.

Thus, in one embodiment of the present invention, there are provided nucleic acids comprising the coding region for a T-type calcium channel and regulatory sequences associated therewith. Specifically, the T-type calcium channel and associated regulatory sequences comprise CACNA1G. In a more preferred embodiment, the CACNA1G is the human form of the gene. An exemplary CACNA1G gene and associated regulatory sequences is set forth in SEQ ID NO:51.

The invention provides methylated and unmethylated nucleic acid encoding CACNA1G (SEQ ID NO:51). Polynucleotides include DNA, cDNA and RNA sequences which encode CACNA1G polypeptide (SEQ ID NO:52). It is understood that naturally occurring, synthetic, and intentionally manipulated polynucleotides are included. For example, CACNA1G nucleic acid may be subject to site-directed mutagenesis, or the like. The nucleic acid sequences for CACNA1G also include antisense sequences, and sequences encoding dominant negative forms of CACNA1G, as well as sequences encoding functional fragments thereof. It is understood that naturally occurring, synthetic, and intentionally manipulated polynucleotides are included.

Methylated nucleic acid sequences are also provided. For the first time, the present invention provides methylated chemical structures for the following genes: APOB, CACNA1G, CDX2, EGFR, FBN1, GPR37, HSPA6, IQGAP2, KL, PAR2, PITX2, PTCH, SDC1, and SDC4. One of skill in the art can now readily locate the CpG-rich sequences associated with these genes and identify such methylated forms of the genes/regulatory sequences by methods described herein (The gene sequences can be identified in a gene database found at <http://www.ncbi.nlm.nih.gov/UniGene/index.html>). The invention provides CpG-rich regions from the above genes as set forth in SEQ ID Nos:105-119. Thus, in yet another embodiment, the invention provides an isolated nucleic acid molecule having at least one methylated Cytosine of a CpG dinucleotide in a CpG-rich region and encoding a gene selected from APOB, CACNA1G, CDX2, EGFR, FBN1, GPR37, HSPA6, IQGAP2, KL, PAR2, PITX2, PTCH, SDC1, and SDC4. The methylated C residue of a CpG dinucleotide is located within a CpG-rich region selected from SEQ ID NO:105-118 and SEQ ID NO:119.

The polynucleotides of the invention include "degenerate variants" which are sequences that encode the same polypeptide yet vary in sequence as a result of the genetic code. There are 20 natural amino acids, most of which are specified by more than one codon. Therefore, all degenerate nucleotide sequences are included in the invention as long as the amino acid sequence of a polypeptide encoded by the nucleotide sequence of SEQ ID NO:51 is functionally unchanged.

The term "polynucleotide" or "nucleic acid sequence" refers to a polymeric form of nucleotides at least 10 bases in length. An "isolated polynucleotide" is a polynucleotide that is not immediately contiguous with both of the coding sequences with which it is immediately contiguous (one on the 5' end and one on the 3' end) in the naturally occurring genome of the organism from which it is derived. Thus, an isolated polynucleotide may include a coding region with its associated regulatory sequences. The term therefore includes, for example, a recombinant DNA which is

incorporated into a vector; into an autonomously replicating plasmid or virus; or into the genomic DNA of a prokaryote or eukaryote, or which exists as a separate molecule (e.g., a cDNA) independent of other sequences. The nucleotides of the invention can be ribonucleotides, deoxyribonucleotides, or modified forms of either
5 nucleotide. Specifically, methylated forms of nucleotides in a polynucleotide sequence, such as regions 1-8 of CACNA1G as described herein, are also included. The term includes single and double forms of DNA.

As will be understood by those of skill in the art, when the sequence is RNA,
10 the deoxynucleotides A, G, C, and T of SEQ ID NO:51, are replaced by ribonucleotides A, G, C, and U, respectively. Also included in the invention are fragments of the above-described nucleic acid sequences that are at least 15 bases in length, which is sufficient to permit the fragment to selectively hybridize to DNA that encodes SEQ ID NO:52. The term "selectively hybridize" refers to hybridization
15 under moderately or highly stringent conditions (See, Maniatis, as cited herein) which excludes non-related nucleotide sequences.

The CACNA1G nucleic acid sequence includes the disclosed sequence and sequences that encode conservative variations of the polypeptides encoded by
20 CACNA1G polynucleotide provided herein. The term "conservative variation" as used herein denotes the replacement of an amino acid residue by another, biologically similar residue. Examples of conservative variations include the substitution of one hydrophobic residue such as isoleucine, valine, leucine or methionine for another, or the substitution of one polar residue for another, such as the substitution of arginine
25 for lysine, glutamic for aspartic acid, or glutamine for asparagine, and the like. The term "conservative variation" also includes the use of a substituted amino acid in place of an unsubstituted parent amino acid provided that antibodies raised to the substituted polypeptide also immunoreact with the unsubstituted polypeptide.

CACNA1G nucleic acid sequences can be expressed in vitro by DNA transfer into a suitable host cell. "Host cells" are cells in which a vector can be propagated and its DNA expressed. The cell may be prokaryotic or eukaryotic. The term also includes any progeny of the subject host cell. It is understood that all progeny may not be identical to the parental cell since there may be mutations that occur during replication. However, such progeny are included when the term "host cells" is used. Methods of stable transfer, meaning that the foreign DNA is continuous-ly maintained in the host, are known in the art.

10 In one aspect, the CACNA1G nucleic acid sequences may be inserted into an expression vector. The term "expression vector" refers to a plasmid, virus or other vehicle known in the art that has been manipulated by insertion or incorporation of the sequence of interest genetic sequences. Polynucleotide sequence which encode sequence of interest can be operatively linked to expression control sequences.

15 "Operatively linked" refers to a juxtaposition wherein the components so described are in a relationship permitting them to function in their intended manner. An expression control sequence operatively linked to a coding sequence is ligated such that expression of the coding sequence is achieved under conditions compatible with the regulatory or expression control sequences. As used herein, the terms "regulatory sequences" and "expression control sequences" refers to nucleic acid sequences that regulate the expression of a nucleic acid sequence to which it is operatively linked.

20 Expression control sequences are operatively linked to a nucleic acid sequence when the expression control sequences control and regulate the transcription and, as appropriate, translation of the nucleic acid sequence. Thus expression control sequences can include appropriate promoters, enhancers, transcription terminators, a start codon (i.e., ATG) in front of a protein-encoding gene, splicing signal for introns, maintenance of the correct reading frame of that gene to permit proper translation of mRNA, and stop codons. The terms "regulatory sequences" and "expression control sequences" are intended to include, at a minimum, components whose presence can influence expression, and can also include additional components whose presence is

25 30

advantageous, for example, leader sequences and fusion partner sequences. An example of an expression control sequence includes a promoter.

A "promoter" is a minimal sequence sufficient to direct transcription. Also
5 included in the invention are those promoter elements which are sufficient to render promoter-dependent gene expression controllable for cell-type specific, tissue-specific, or inducible by external signals or agents; such elements may be located in the 5' or 3' regions of the gene. Both constitutive and inducible promoters, are included in the invention (see, e.g., Bitter et al., *Methods in Enzymology* 153:516-
10 544, 1987). For example, when cloning in bacterial systems, inducible promoters such as pL of bacteriophage plac, ptrp, ptac (ptrp-lac hybrid promoter) and the like may be used. When cloning in mammalian cell systems, promoters derived from the genome of mammalian cells (e.g., metallothionein promoter) or from mammalian viruses (e.g., the retrovirus long terminal repeat; the adenovirus late promoter; the
15 vaccinia virus 7.5K promoter) may be used. Promoters produced by recombinant DNA or synthetic techniques may also be used to provide for transcription of the nucleic acid sequences of the invention.

In the present invention, the CACNA1G polynucleotide sequence may be
20 inserted into an expression vector which contains a promoter sequence which facilitates the efficient transcription of the inserted genetic sequence of the host. The expression vector typically contains an origin of replication, a promoter, as well as specific genes which allow phenotypic selection of the transformed cells. Vectors suitable for use in the present invention include, but are not limited to the T7-based
25 expression vector for expression in bacteria (Rosenberg et al., *Gene* 56:125, 1987), the pMSXND expression vector for expression in mammalian cells (Lee and Nathans, *J. Biol. Chem.* 263:3521, 1988) and baculovirus-derived vectors for expression in insect cells. The DNA segment can be present in the vector operably linked to regulatory elements, for example, a promoter (e.g., T7, metallothionein I, or polyhedron
30 promoters).

CACNA1G polynucleotide sequences can be expressed in either prokaryotes or eukaryotes. Hosts can include microbial, yeast, insect and mammalian organisms. Methods of expressing DNA sequences having eukaryotic or viral sequences in prokaryotes are well known in the art. Biologically functional viral and plasmid DNA
5 vectors capable of expression and replication in a host are known in the art. Such vectors are used to incorporate DNA sequences of the invention.

“Transformation” means a genetic change induced in a cell following incorporation of new DNA (i.e., DNA exogenous to the cell). Where the cell is a
10 mammalian cell, the genetic change is generally achieved by introduction of the DNA into the genome of the cell (i.e., stable).

Thus, a “transformed cell” is a cell into which (or into an ancestor of which) has been introduced, by means of recombinant DNA techniques, a DNA molecule
15 encoding sequence of interest. Transformation of a host cell with recombinant DNA may be carried out by conventional techniques as are well known to those skilled in the art. Where the host is prokaryotic, such as *E. coli*, competent cells which are capable of DNA uptake can be prepared from cells harvested after exponential growth phase and subsequently treated by the CaCl_2 method using procedures well known in
20 the art. Alternatively, MgCl_2 or RbCl can be used. Transformation can also be performed after forming a protoplast of the host cell if desired.

When the host is a eukaryote, such methods of transfection of DNA as calcium phosphate co-precipitates, conventional mechanical procedures such as
25 microinjection, electroporation, insertion of a plasmid encased in liposomes, or virus vectors may be used. Eukaryotic cells can also be cotransformed with DNA sequences encoding the sequence of interest, and a second foreign DNA molecule encoding a selectable phenotype, such as the herpes simplex thymidine kinase gene. Another method is to use a eukaryotic viral vector, such as simian virus 40 (SV40) or bovine
30 papilloma virus, to transiently infect or transform eukaryotic cells and express the

protein (see for example, Eukaryotic Viral Vectors, Cold Spring Harbor Laboratory, Gluzman ed., 1982).

Methods which are well known to those skilled in the art can be used to
5 construct expression vectors containing the CACNA1G coding sequence and
appropriate transcriptional/translational control signals. These methods include in
vitro recombinant DNA techniques, synthetic techniques, and in vivo
recombination/genetic techniques. See, for example, the techniques described in
Maniatis, et al., 1989 Molecular Cloning A Laboratory Manual, Cold Spring Harbor
10 Laboratory, N.Y.

A variety of host-expression vector systems may be utilized to express the
CACNA1G coding sequence. These include but are not limited to microorganisms
such as bacteria transformed with recombinant bacteriophage DNA, plasmid DNA or
15 cosmid DNA expression vectors containing the CACNA1G coding sequence; yeast
transformed with recombinant yeast expression vectors containing the CACNA1G
coding sequence; plant cell systems infected with recombinant virus expression
vectors (e.g., cauliflower mosaic virus, CaMV; tobacco mosaic virus, TMV) or
transformed with recombinant plasmid expression vectors (e.g., Ti plasmid)
20 containing the CACNA1G coding sequence; insect cell systems infected with
recombinant virus expression vectors (e.g., baculovirus) containing the CACNA1G
coding sequence; or animal cell systems infected with recombinant virus expression
vectors (e.g., retroviruses, adenovirus, vaccinia virus) containing the CACNA1G
coding sequence, or transformed animal cell systems engineered for stable expression.
25 Since CACNA1G has not been confirmed to contain carbohydrates, both bacterial
expression systems as well as those that provide for translational and post-
translational modifications may be used; e.g., mammalian, insect, yeast or plant
expression systems.

30 Depending on the host/vector system utilized, any of a number of suitable
transcription and translation elements, including constitutive and inducible promoters,

transcription enhancer elements, transcription terminators, etc. may be used in the expression vector (see e.g., Bitter, et al., *Methods in Enzymology* 153:516-544, 1987). For example, when cloning in bacterial systems, inducible promoters such as pL of bacteriophage .gamma., plac, ptrp, ptac (ptrp-lac hybrid promoter) and the like may be
5 used. When cloning in mammalian cell systems, promoters derived from the genome of mammalian cells (e.g., metallothionein promoter) or from mammalian viruses(e.g., the retrovirus long terminal repeat; the adenovirus late promoter; the vaccinia virus 7.5K promoter) may be used. Promoters produced by recombinant DNA or synthetic techniques may also be used to provide for transcription of the inserted CACNA1G
10 coding sequence. In addition, the endogenous CACNA1G promoter may also be used to provide transcription machinery of CACNA1G .

In bacterial systems a number of expression vectors may be advantageously selected depending upon the use intended for the expressed. For example, when large
15 quantities of CACNA1G are to be produced, vectors which direct the expression of high levels of fusion protein products that are readily purified may be desirable. Those which are engineered to contain a cleavage site to aid in recovering are preferred. Such vectors include but are not limited to the E. coli expression vector pUR278 (Ruther, et al., *EMBO J.* 2:1791, 1983), in which the CACNA1G coding sequence
20 may be ligated into the vector in frame with the lac Z coding region so that a hybrid - lac Z protein is produced; pIN vectors (Inouye & Inouye, *Nucleic Acids Res.*, 13:3101-3109, 1985; Van Heeke & Schuster, *J. Biol. Chem.* 264:5503-5509, 1989); glutathione-S-transferase (GST) and the like.

25 In yeast, a number of vectors containing constitutive or inducible promoters may be used. For a review see, *Current Protocols in Molecular Biology*, Vol. 2, 1988, Ed. Ausubel, et al., Green Publish. Assoc. & Wiley Interscience, Ch. 13; Grant, et al., 1987, *Expression and Secretion Vectors for Yeast*, in *Methods in Enzymology*, Eds. Wu & Grossman, 31987, Acad. Press, N.Y., Vol. 153, pp. 516-544; Glover, 1986,
30 *DNA Cloning*, Vol. II, IRL Press, Wash., D.C., Ch. 3; and Bitter, 1987, *Heterologous*

Gene Expression in Yeast, Methods in Enzymology, Eds. Berger & Kimmel, Acad. Press, N.Y., Vol. 152, pp. 673-684; and The Molecular Biology of the Yeast *Saccharomyces*, 1982, Eds. Strathern, et al., Cold Spring Harbor Press, Vols. I and II. A constitutive yeast promoter such as ADH or LEU2 or an inducible promoter such as GAL may be used (Cloning in Yeast, Ch. 3, R. Rothstein In: DNA Cloning Vol.11, A Practical Approach, Ed. DM Glover, 1986, IRL Press, Wash., D.C.). Alternatively, vectors may be used which promote integration of foreign DNA sequences into the yeast chromosome.

10 In cases where plant expression of the CACNA1G coding sequence may be driven by any of a number of promoters. For example, viral promoters such as the 35S RNA and 19S RNA promoters of CaMV (Brisson, et al., Nature 310:511-514, 1984), or the coat protein promoter to TMV (Takamatsu, et al., EMBO J.6:307-311, 1987) may be used; alternatively, plant promoters such as the small subunit of RUBISCO (Coruzzi, et al., EMBO J.3:1671-1680, 1984; Broglie, et al., Science 224:838-843, 15 1984); or heat shock promoters, e.g., soybean hsp17.5-E or hsp17.3-B (Gurley, et al., Mol. Cell. Biol. 6:559-565, 1986) may be used. These constructs can be introduced into plant cells using Ti plasmids, Ri plasmids, plant virus vectors, direct DNA transformation, microinjection, electroporation, etc. For reviews of such techniques 20 see, for example, Weissbach & Weissbach, 1988, Methods for Plant Molecular Biology, Academic Press, N.Y., Section VIII, pp. 421-463; and Grierson & Corey, 1988, Plant Molecular Biology, 2d Ed., Blackie, London, Ch. 7-9.

An alternative expression system which could be used to express is an insect 25 system. In one such system, *Autographa californica* nuclear polyhedrosis virus (AcNPV) is used as a vector to express foreign genes. The virus grows in *Spodoptera frugiperda* cells. The CACNA1G coding sequence may be cloned into non-essential regions (for example the polyhedrin gene) of the virus and placed under control of an AcNPV promoter (for example the polyhedrin promoter). Successful insertion of the 30 CACNA1G coding sequence will result in inactivation of the polyhedrin gene and

production of non-occluded recombinant virus (i.e., virus lacking the proteinaceous coat coded for by the polyhedrin gene). These recombinant viruses are then used to infect *Spodoptera frugiperda* cells in which the inserted gene is expressed. (e.g., see Smith, et al., 1983, J. Virol. 46:584; Smith, U.S. Pat. No. 4,215,051).

5

Eukaryotic systems, and preferably mammalian expression systems, allow for proper post-translational modifications of expressed mammalian proteins to occur. Eukaryotic cells which possess the cellular machinery for proper processing of the primary transcript, glycosylation, phosphorylation, and advantageously, secretion of the gene product may be used as host cells for the expression of CACNA1G .
10 Mammalian cell lines may be preferable. Such host cell lines may include but are not limited to CHO, VERO, BHK, HeLa, COS, MDCK, -293, and W138.

Mammalian cell systems which utilize recombinant viruses or viral elements to direct expression may be engineered. For example, when using adenovirus
15 expression vectors, the CACNA1G coding sequence may be ligated to an adenovirus transcription/translation control complex, e.g., the late promoter and tripartite leader sequence. This chimeric gene may then be inserted in the adenovirus genome by in vitro or in vivo recombination. Insertion in a non-essential region of the viral genome
20 (e.g., region E1 or E3) will result in a recombinant virus that is viable and capable of expressing the protein in infected hosts (e.g., see Logan & Shenk, Proc. Natl. Acad. Sci. USA, 81:3655-3659, 1984). Alternatively, the vaccinia virus 7.5K promoter may be used (e.g., see, Mackett, et al., 1982, Proc. Natl. Acad. Sci. USA 79:7415-7419; Mackett, et al., J. Virol. 49:857-864, 1984; Panicali, et al., Proc. Natl. Acad. Sci. USA
25 79:4927-4931, 1982). Of particular interest are vectors based on bovine papilloma virus which have the ability to replicate as extrachromosomal elements (Sarver, et al., Mol. Cell. Biol. 1:486, 1981). Shortly after entry of this DNA into mouse cells, the plasmid replicates to about 100 to 200 copies per cell. Transcription of the inserted cDNA does not require integration of the plasmid into the host's chromosome, thereby
30 yielding a high level of expression. These vectors can be used for stable expression by

including a selectable marker in the plasmid, such as, for example, the neo gene. Alternatively, the retroviral genome can be modified for use as a vector capable of introducing and directing the expression of the CACNA1G gene in host cells (Cone & Mulligan, Proc. Natl. Acad. Sci. USA 81:6349-6353, 1984). High level expression
5 may also be achieved using inducible promoters, including, but not limited to, the metallothionine IIA promoter and heat shock promoters.

For long-term, high-yield production of recombinant proteins, stable expression is preferred. Rather than using expression vectors which contain viral
10 origins of replication, host cells can be transformed with the CACNA1G cDNA controlled by appropriate expression control elements (e.g., promoter, enhancer, sequences, transcription terminators, polyadenylation sites, etc.), and a selectable marker. The selectable marker in the recombinant plasmid confers resistance to the selection and allows cells to stably integrate the plasmid into their chromosomes and
15 grow to form foci which in turn can be cloned and expanded into cell lines. For example, following the introduction of foreign DNA, engineered cells may be allowed to grow for 1-2 days in an enriched media, and then are switched to a selective media. A number of selection systems may be used, including but not limited to the herpes simplex virus thymidine kinase (Wigler, et al., Cell, 11:223, 1977), hypoxanthine-
20 guanine phosphoribosyltransferase (Szybalska & Szybalski, Proc. Natl. Acad. Sci. USA, 48:2026, 1962), and adenine phosphoribosyltransferase (Lowy, et al., Cell, 22: 817, 1980) genes can be employed in tk.sup.-, hgppt.sup.- or appt.sup.- cells respectively. Also, antimetabolite resistance can be used as the basis of selection for dhfr, which confers resistance to methotrexate (Wigler, et al., Natl. Acad. Sci. USA,
25 77:3567, 1980; O'Hare, et al., Proc. Natl. Acad. Sci. USA, 78: 1527, 1981); gpt, which confers resistance to mycophenolic acid (Mulligan & Berg, Proc. Natl. Acad. Sci. USA, 78: 2072, 1981; neo which confers resistance to the aminoglycoside G-418 (Colberre-Garapin, et al., J. Mol. Biol., 150:1, 1981); and hygromycin (Santerre, et al., Gene, 30:147, 1984) genes. Recently,
30 additional selectable genes have been described, namely tpkB, which allows cells to

utilize indole in place of tryptophan; hisD, which allows cells to utilize histinol in place of histidine (Hartman & Mulligan, Proc. Natl. Acad. Sci. USA, 85:8047, 1988); and ODC (ornithine decarboxylase) which confers resistance to the ornithine decarboxylase inhibitor, 2-(difluoromethyl)-DL-ornithine, DFMO (McConlogue L.,
5 1987, In: Current Communications in Molecular Biology, Cold Spring Harbor Laboratory, ed.).

Isolation and purification of microbial expressed polypeptide, or fragments thereof, provided by the invention, may be carried out by conventional means
10 including preparative chromatography and immunological separations involving monoclonal or polyclonal antibodies.

In one embodiment, the invention provides substantially purified polypeptide encoded by CACNA1G polynucleotide sequences. Exemplary CACNA1G
15 polypeptide is set forth in SEQ ID NO:52. The term "substantially purified" as used herein refers to a polypeptide which is substantially free of other proteins, lipids, carbohydrates or other materials with which it is naturally associated. One skilled in the art can purify a polypeptide encoded by CACNA1G polynucleotide sequence using standard techniques for protein purification. The substantially pure polypeptide
20 will yield a single major band on a non-reducing polyacrylamide gel. The purity of the CACNA1G polypeptide can also be determined by amino-terminal amino acid sequence analysis.

Minor modifications of the CACNA1G primary amino acid sequences may
25 result in proteins which have substantially equivalent activity as compared to the unmodified counterpart polypeptide described herein. Such modifications may be deliberate, as by site-directed mutagenesis, or may be spontaneous. All of the polypeptides produced by these modifications are included herein as long as the biological activity still ex-ists.

The polypeptides of the invention also include dominant negative forms of the CACNA1G polypeptide which do not have the biological activity of CACNA1G polypeptide sequence. A "dominant negative form" of CACNA1G is a polypeptide that is structurally similar to CACNA1G polypeptide but does not have wild-type CACNA1G function. For example, a dominant-negative CACNA1G polypeptide may interfere with wild-type CACNA1G function by binding to, or otherwise sequestering, regulating agents, such as upstream or downstream components, that normally interact functionally with the CACNA1G polypeptide.

10 Identification and Isolation of CACNA1G

To identify genes differentially methylated in colorectal cancer, methylated CpG island amplification was used followed by representational difference analysis (Razin and Cedar, Cell 17: 473-476, 1994, herein incorporated by reference). One of the clones recovered (MINT31, see U.S. Patent Application Serial No. 09/309,175, incorporated by reference herein in its entirety) mapped to human chromosome 17q21 using a radiation hybrid panel. A Blast search revealed this fragment to be completely identical to part of a BAC clone (Genbank: AC004590) sequenced by high throughput genomic sequencing. The region surrounding MINT31 fulfills the criteria of a CpG island: GC content 0.67, CpG/GpC ratio 0.78 and a total of 305 CpG sites in a 4 kb region. Using this CpG island and 10 kb of flanking sequences in a Blast analysis, several regions highly homologous to the rat T-type calcium channel gene, CACNA1G, were identified (Perez-Reyes et al., Nature 391: 896-900, 1998, herein incorporated by reference). Several ESTs were also identified in this region. Using Genscan, 2 putative coding sequences (G1, and G2) were identified. Blastp analysis revealed that G1 has a high homology to the EH-domain-binding protein, epsin, while G2 is homologous to a C. elegans hypothetical protein (accession No. 2496828).

The MINT31 CpG island corresponds to the 3' regions of G1 and G2, based on the direction of the open reading frame and the presence of a poly A tail, and, without

being bound by theory, is unlikely to influence their transcription. The EST closest to MINT31 (H13333) (SEQ ID NO:120; Figure 5) was sequenced entirely and was found not to contain a continuous open reading frame, but a poly-adenylation signal was identified on one end, along with a poly A tail. These data suggest that H13333
5 corresponds to the last 2 exons of an unidentified gene. MINT31 is in the intron of this gene and is, again without being bound by theory, unlikely to influence transcription of the unidentified gene. However, based on both promoter prediction (TSSG) analysis of this region and homology to the rat CACNA1G sequence, the MINT31 CpG island is also in the 5' region of human CACNA1G gene and is likely
10 to play a role in its transcriptional activity.

The human CACNA1G sequence deposited in Genbank lacks the 5' region of the gene, when compared to the rat homologue. To determine the 5' region of human CACNA1G, cDNA was amplified by RT-PCR using primers based on the BAC
15 sequence (Genbank: AC004590, herein incorporated by reference). The PCR products were cloned and sequenced, and the genomic organization of the gene was determined by comparing the newly identified sequences as well as the known sequences to the BAC that covers this region. CACNA1G is composed of 34 exons which span a 70 kb area. (See, Figure 3A and SEQ ID NO:52). Based on sequences deposited in
20 Genbank, the gene has two possible 3' ends caused by alternate splicing. Human CACNA1G is highly homologous to rat CACNA1G with 93% identity at the protein level, and 89% identity at the nucleotide level. The 5' flanking region of human CACNA1G lacks TATA and CAAT boxes, which is similar to many housekeeping genes. A putative TFIID binding site was identified 547-556 bp upstream from the
25 translation start site, and several other potential transcription factor binding sites such as AP1 (1 site), AP2 (2 sites) and SP1 (10 sites), were identified upstream of CACNA1G exon 1 using the promoter prediction program, TESS.

Methylation Analysis of CACNA1G

The CACNA1G CpG island is 4 kb, and is larger than many typical CpG islands. MINT31 corresponds to the 5' edge of the island while CACNA1G is in the 3' region. It is not known whether large CpG islands such as this are coordinately regulated with regards to protection from methylation, and aberrant methylation in cancer.

To address this issue, the methylation status of the 5' region of CACNA1G was studied using bisulfite-PCR of DNA from normal tissues as well as 35 human cancer cell lines from colon, lung, prostate, breast and hematopoietic tumors. More specifically, forty-nine primary colorectal cancers, 28 colorectal adenomas, 16 primary gastric cancers and 17 acute myelogenous leukemia samples were used for methylation analyses. DNA from eight colon cancer cell lines (Caco2, RKO, SW48, HCT116, DLD1, Lovo, SW837, HT29), 4 lung cancer cell lines (OH3, H249, H157, H209), 4 glioblastoma cell lines (Dauy, D283, U87, U373), 8 breast cancer cell lines (MB-468, MCF7, MB-231, MB-474, MB-435, MB-453, BT20, CAMA1, SKBR3), 7 hematopoietic tumor cell lines (CEM, Raji, KG1A, HL60, ML-1, MoIt3, K562), and 4 prostate cancer cell lines (DU145, DUPRO, LNCAP, TSUPRL) were also investigated. The CpG island was divided into 8 regions (SEQ ID NOs: 35-42, respectively). The methylation status of each region was examined separately. The genomic DNA was treated with sodium bisulfite and PCR amplified using primers containing no or a minimum number of CpG sites. (For a detailed description of bisulfite-PCR, see, U.S. Patent No. 5,786,146, incorporated herein by reference in its entirety). Methylated alleles were detected by digesting the PCR products using restriction enzymes which specifically cleave sites created or retained due to the presence of methylated CpGs. None of the regions was methylated in normal colon, consistent with a uniform protection against de-novo methylation.

Regions 1 and 2 were frequently methylated in cancer cell lines, and behaved in a concordant manner with respect to methylation pattern. Indeed, these 2 regions were methylated in most cancer cell types except gliomas. Moreover, most cell lines where methylation was found methylated both regions 1 and 2. in contrast, region 3, which is less CG rich than any of the other regions, had either no methylation or very low levels of methylation in most cell lines. Regions 5, 6, and 7 behaved quite differently compared to 1-3. Methylation of these regions was less frequent than regions 1-2, as 22/35 cell lines had no detectable methylation there, despite often showing methylation of region 1-2. However, when methylation of regions 5, 6, or 7 was present (in 13/35 cell lines), it affected all 3 regions in a coordinate manner, although to varying extents. Finally, regions 4 and 8 behaved differently again, being partially methylated primarily in colon and breast cell lines. Therefore, with regards to hypermethylation in cancer cells, the CpG rich region upstream of CACNA1G appears to be composed of 2 CpG islands which behave independently. MINT31 corresponds to the upstream CpG island (island 1, regions 1 and 2), while the 5' region of CACNA1G is contained in the downstream CpG island (island 2, regions 5-7). Regions 3, 4 and 8 correspond to the edge of these CpG islands, and behave a little differently than the hearts of the CpG islands, as previously described for the E-Cad gene (Graff, et al., J. Biol. Chem. 272: 22322-22329, 1997).

20

Overall, the methylation patterns of CACNA1G fell into 5 distinct categories: (1) No methylation in any region (normal tissue). (2) Slight methylation of island 1 (6 cell lines, e.g., TSU-PRL). (3) Heavy methylation of island 1 but no methylation of island 2 (16 cell lines, e.g., Caco2). (4) Heavy methylation of island 1 and moderate to heavy methylation of island 2 (6 cell lines, e.g., RKO and Raji). (5) High methylation of island 1 and low to moderate methylation of island 2 (7 cell lines, e.g., MB-231).

30

Methylation Dependent Expression of CACNA1G

In a previous study, rat CACNA1G was shown to be expressed most abundantly in the brain (Perez-Reyes et al., Nature 391: 896-900. 1998). To determine the expression of CACNA1G in normal and neoplastic human cells, RT-PCR was performed using cDNA from various normal tissues and from a panel of 27 tumor cell lines. CACNA1G was expressed ubiquitously in a variety of tissues and cell lines. In normal tissues expression was relatively low but easily detectable, while most cell lines had relatively high expression of CACNA1G. However, some cell lines had negligible or totally absent levels of CACNA1G expression. The results of CACNA1G expression was correlated with the detailed methylation analysis previously described. In this analysis, a remarkable pattern emerged. Methylation of regions 1-4 and 8 had no effect on CACNA1G expression. However, there was a strong correlation between methylation of regions 5-7 and expression of the gene. In fact, all cell lines tested that lack methylation of this region strongly express the gene. All 6 cell lines with pattern 4 methylation studied had no detectable expression. Finally, the 7 cell lines with pattern 5 methylation (examples DLD-1 and MB-453) had variable levels of expression ranging from very low to near normal. The fact that patterns 3 and 5 differ significantly with regards to expression, but are almost identical with regards to methylation of all regions except 7 indicates that this area is important in the inactivation of CACNA1G.

To confirm that methylation of the 5' CpG island of CACNA1G is associated with gene inactivation, 3 non-expressing cell lines showing pattern 4 methylation (RKO, SW48 and Raji) and 2 weakly expressing cell lines showing pattern 5 methylation (MB-231 and MB-435) were treated with 1 M of the methyl-transferase inhibitor 5-deoxy-azacitidine. After treatment, all of these cell lines re-expressed CACNA1G mRNA. Consistent with re-expression, demethylation of region 7 was observed after 5-deoxy-azacitidine treatment.

De novo cytosine methylation is thought to sometimes occur in vitro during cell propagation (Antequera et al., Cell 62: 503-514, 1990). To determine whether the methylation of CACNA1G occurs in vivo, primary human tumors were examined for methylation of the 5' region of CACNA1G. Aberrant methylation was detected in 17
5 out of 49 (35%) colorectal cancers, 4 out of 28 colorectal adenomas (25%), 4 out of 16 (25%) gastric cancers and 3 out of 17 (18%) acute myelogenous leukemia cases. In colorectal cancers, there was a significant correlation between methylation of CACNA1G and methylation of p16 ($p < 0.005$) and hMLH1 ($p < 0.001$), as well as a strong correlation with the presence of microsatellite instability, and the recently
10 identified CpG island methylator phenotype (CIMP), indicating that CACNA1G is also a target for CIMP in colorectal cancer.

To determine whether aberrant methylation of the 5' region of CACNA1G affects the expression status of this gene in primary tumors, RT-PCR was performed
15 using cDNA from a series of colorectal adenomas. Six out of 8 cases which showed no methylation of region 7 expressed CACNA1G. In sharp contrast, all 5 cases that showed methylation of region 7 had no detectable expression of the gene.

Thus, a human T-type calcium channel gene (CACNA1G) has been identified
20 and cloned using the MINT31 sequence as a probe. The human T-type calcium channel gene has been determined to be a target of aberrant methylation and silencing in human tumors. The data show that MINT31 (for a representative sequence of MINT1-33, see, US Patent Application Serial No. 09/309,175) hereby incorporated by reference can be used as a probe to identify genes that play a role in disorders such as
25 cell proliferative disorders.

Detailed analysis of the CpG island upstream of CACNA1G revealed that methylation 300 to 800 bp upstream of the gene closely correlated with transcriptional inactivation. The CACNA1G promoter is contained in a large CG rich area that is not
30 coordinately methylated in cancer. The CpG island around MINT31 is much more

frequently methylated in cancers compared to that just upstream of CACNA1G. This may simply be caused by differential susceptibility to de-novo methylation between these two regions, with methylation of MINT31 serving as a trigger, and eventually spreading to CACNA1G, as described in other genes (Graff, et al., J. Biol. Chem. 272: 22322-22329, 1997). However, it is likely that these 2 regions are controlled by different mechanisms because (1) cell lines kept in culture for countless generations do not in fact spread methylation from MINT31 to CACNA1G (e.g., Caco2), (2) region 3 that separates the 2 islands is infrequently and sparsely methylated in cancer and (3) 2 cases of primary colorectal cancer were found which are methylated at the CACNA1G promoter but not at MINT31). Therefore, methylation of MINT31 appears to be independent of methylation of CACNA1G suggesting that they are 2 distinct CpG islands regulated by different mechanisms.

Many CpG islands of silenced genes appear to be methylated uniformly and heavily throughout the island (e.g., Graff, et al., J. Biol. Chem. 272: 22322-22329, 1997). In contrast the methylation patterns of the 5' region of CACNA1G (region 5-7) was heterogeneous in the cell lines which did not express this gene. Nevertheless, methylation clearly plays a role in CACNA1G repression since demethylation readily reactivates the gene.

The mechanism of CACNA1G methylation remains to be determined. Methylation was not detected in normal colon mucosa, placenta, normal breast epithelium and normal bone marrow, including samples from aged patients, suggesting that methylation of this region is specific for cell proliferative disorders such as cancer, and the like. However, there was a significant correlation between methylation of CACNA1G and other tumor suppressor genes such as p16 and hMLH1. Thus, CACNA1G is likely a target for the recently described CIMP phenotype, which results in a form of epigenetic instability with simultaneous inactivation of multiple genes.

T-type calcium channels are involved not only in electrophysiological rhythm generation but also in the control of cytosolic calcium during cell proliferation and cell death (reviewed in Berridge, et al., *Nature* 395: 645-648, 1998). Expression of CACNA1G is not limited to brain and heart, indicating a likely role in other tissues in which it is expressed. It has previously been shown that Ca²⁺ influx via T-type channels is an important factor during the initial stages of cell death such as apoptosis (Berridge, et al., *Nature* 395: 645-648, 1998), ischemia (Fern, J. *Neurosci.* 18: 7232-7243, 1998) and complement-induced cytotoxicity (Newsholme, et al., *Biochem. J.* 295: 773-779, 1993.). The studies culminating in the present invention indicates that impairment of voltage gated calcium channels plays an important role in cancer development and progression through altering calcium signaling.

Due to the clear correlation between methylation of CpG islands and cellular proliferative disorders, in another embodiment of the present invention, there are provided methods for detecting a cellular proliferative disorder in a subject having or at risk for said cellular proliferative disorder. The method includes assaying, in nucleic acid-containing specimen taken from said subject, the methylation state of a gene or its associated regulatory regions, wherein the expression state of the gene or its associated regulatory regions is associated with the presence of the cellular proliferative disorder, and identifying as having a cellular proliferative disorder a subject that has aberrant methylation of regions of said gene. The method provides for detecting a cellular proliferative disorder in a subject having or at risk for said cellular proliferative disorder by identifying aberrantly methylation of regions of a gene when compared to the same regions of the gene in a subject not having said cellular proliferative disorder.

The aberrant methylation comprises hypermethylated CpG rich regions (i.e., islands). In one aspect of the present invention, the CpG rich regions are associated with the CACNA1G gene, and affect the expression thereof in a methylation state-dependent manner. A "cell proliferative disorder" or "cellular proliferative disorder"

is any disorder in which the proliferative capabilities of the affected cells is different from the normal proliferative capabilities of unaffected cells. An example of a cell proliferative disorder is neoplasia. Malignant cells (i.e., cancer) develop as a result of a multistep process. Specific, non-limiting examples of cell proliferative disorders associated with increased methylation of CpG-islands are low grade astrocytoma, anaplastic astrocytoma, glioblastoma, medulloblastoma, gastric cancer, colorectal cancer, colorectal adenoma, acute myelogenous leukemia, lung cancer, renal cancer, leukemia, breast cancer, prostate cancer, endometrial cancer and neuroblastoma.

10 A cell proliferative disorder as described herein may be a neoplasm. Such neoplasms are either benign or malignant. The term "neoplasm" refers to a new, abnormal growth of cells or a growth of abnormal cells that reproduce faster than normal. A neoplasm creates an unstructured mass (a tumor) which can be either benign or malignant. For example, the neoplasm may be a head, neck, lung, esophageal, stomach, prostate, small bowel, colon, bladder, kidney, or cervical neoplasm. The term "benign" refers to a tumor that is noncancerous, e.g. its cells do not proliferate or invade surrounding tissues. The term "malignant" refers to a tumor that is metastatic or no longer under normal cellular growth control.

20 A cell proliferative disorder may be an age-associated disorder. Examples of age-associated disorders which are cell proliferative disorders include colon cancer, lung cancer, breast cancer, prostate cancer, leukemia and melanoma, amongst others.

A "nucleic acid containing specimen" includes any type of material containing a nucleic acid to be subject to invention methods. The nucleic acid may be contained in a biological sample. Such samples include but are not limited to any bodily fluid, such as a serum, urine, saliva, blood, cerebrospinal fluid, pleural fluid, ascites fluid, sputum, stool, or a biopsy sample.

30 Samples or specimens include any CpG-rich DNA sequence, whatever the origin, as long as the sequence is detectably present in a sample. While routine

diagnostic tests may not be able to identify cancer cells in these samples, the method of the present invention identifies neoplastic cells derived from the primary tumor or from a metastases. The method includes non-invasive sampling (e.g., bodily fluid) as well as invasive sampling (e.g., biopsy). The sample of DNA of the subject may be

5 serum, plasma, lymphocytes, urine, sputum, bile, stool, cervical tissue, saliva, tears, cerebral spinal fluid, regional lymph node, histopathologic margins, and any bodily fluid that drains a body cavity or organ. Therefore, the method provides for the non-invasive detection of various tumor types including head and neck cancer, lung cancer, esophageal cancer, stomach cancer, small bowel cancer, colon cancer, bladder

10 cancer, kidney cancers, cervical cancer and any other organ type that has a draining fluid accessible to analysis. For example, neoplasia of regional lymph nodes associated with a primary mammary tumor can be detected using the method of the invention. Regional lymph nodes for head and neck carcinomas include cervical lymph nodes, prelaryngeal lymph nodes, pulmonary juxta-esophageal lymph nodes

15 and submandibular lymph nodes. Regional lymph nodes for mammary tissue carcinomas include the axillary and intercostal nodes. Samples also include urine DNA for bladder cancer or plasma or saliva DNA for head and neck cancer patients.

Any nucleic acid sample, in purified or nonpurified form, can be utilized as the

20 starting nucleic acid or acids in accordance with the present invention, provided it contains, or is suspected of containing, a nucleic acid sequence containing a target locus (e.g., CpG-containing nucleic acid). In general, the CpG-containing nucleic acid is DNA. However, invention methods may employ, for example, samples that contain DNA, or DNA and RNA, including messenger RNA, wherein DNA or RNA

25 may be single stranded or double stranded, or a DNA-RNA hybrid may be included in the sample. A mixture of nucleic acids may also be employed. The specific nucleic acid sequence to be detected may be a fraction of a larger molecule or can be present initially as a discrete molecule, so that the specific sequence constitutes the entire nucleic acid. It is not necessary that the sequence to be studied be present initially in a

30 pure form; the nucleic acid may be a minor fraction of a complex mixture, such as

contained in whole human DNA. The nucleic acid-containing sample used for detection of methylated CpG may be from any source including, but not limited to, brain, colon, urogenital, lung, renal, pancreas, liver, esophagus, stomach, hematopoietic, breast, thymus, testis, ovarian, prostate and uterine tissue, and may be
5 extracted by a variety of techniques such as that described by Maniatis, et al. (Molecular Cloning: a Laboratory Manual, Cold Spring Harbor, NY, pp 280, 281, 1982).

The nucleic acid of interest can be any nucleic acid where it is desirable to
10 detect the presence of a differentially methylated CpG island. The CpG island comprises a CpG island located in a gene or regulatory region for a gene. A "CpG island" is a CpG rich region of a nucleic acid sequence. The nucleic acid sequence may include, for example, APOB, CACNA1G, CDX2, EGFR, FBN1, GPR37, HSPA6, IQGAP2, KL, PAR2, PITX2, PTCH, SDC1, or SDC4 (see for example
15 Figures 4A-4F). Alternatively the nucleic acid of interest can be, for example, a MINT31 nucleic acid sequence (SEQ ID NO:120. However, any gene or nucleic acid sequence of interest containing a CpG sequence can provide diagnostic information (i.e., via its methylation state) using invention methods.

Moreover, these markers can also be multiplexed in a single amplification
20 reaction to generate a low cost, reliable cancer screening test for many cancers simultaneously. A combination of DNA markers for CpG-rich regions of nucleic acid may be amplified in a single amplification reaction. The markers are multiplexed in a single amplification reaction, for example, by combining primers for more than one
25 locus. For example, DNA from a urine sample can be amplified with three different randomly labeled primer sets, such as those used for the amplification of the CACNA1G, EGFR and PTCH loci, in the same amplification reaction. The reaction products are separated on a denaturing polyacrylamide gel, for example, and then exposed to film for visualization and analysis. By analyzing a panel of markers, there
30 is a greater probability of producing a more useful methylation profile for a subject.

If the sample is impure (e.g., plasma, serum, stool, ejaculate, sputum, saliva, cerebrospinal fluid, or blood or a sample embedded in paraffin), it may be treated before amplification with a reagent effective for lysing the cells contained in the fluids, tissues, or animal cell membranes of the sample, and for exposing the nucleic acid(s) contained therein. Methods for purifying or partially purifying nucleic acid from a sample are well known in the art (e.g., Sambrook et al., Molecular Cloning: a Laboratory Manual, Cold Spring Harbor Press, 1989, herein incorporated by reference).

10 In order to detect a differential methylation state for a gene or CpG-containing region of interest, invention methods include any means known in the art for detecting such differential methylation. For example, detecting the differential methylation may include contacting the nucleic acid-containing specimen with an agent that modifies unmethylated cytosine, amplifying a CpG-containing nucleic acid in the specimen by means of CpG-specific oligonucleotide primers, wherein the oligonucleotide primers distinguish between modified methylated and nonmethylated nucleic acid, and detecting the methylated nucleic acid based on the presence or absence of amplification products produced in said amplifying step. This embodiment includes the PCR-based methods described in U.S. Patent No. 5,786,146, incorporated herein in its entirety.

For the first time, the methylation state of a number of genes has been correlated with cell proliferative disorders. Examples of such genes, primers useful for identifying their methylation state, and general PCR conditions are set out in Table 1.

¹ Gene database that can be found at <http://www.ncbi.nlm.nih.gov/UniGene/index.html>.² Examples: List is not comprehensive.³ Two promoters are affected.

In another embodiment, detection of differential methylation is accomplished by contacting a nucleic acid sample suspected of comprising a CpG-containing nucleic acid with a methylation sensitive restriction endonuclease that cleaves only unmethylated CpG sites under conditions and for a time to allow cleavage of unmethylated nucleic acid. The sample is further contacted with an isoschizomer of the methylation sensitive restriction endonuclease, that cleaves both methylated and unmethylated CpG-sites, under conditions and for a time to allow cleavage of methylated nucleic acid. Oligonucleotides are added to the nucleic acid sample under conditions and for a time to allow ligation of the oligonucleotides to nucleic acid cleaved by the restriction endonuclease, and the digested nucleic acid is amplified by conventional methods such as PCR wherein primers complementary to the oligonucleotides are employed. Following identification, the methylated CpG-containing nucleic acid can be cloned, using method well known to one of skill in the art (see Sambrook et al., Molecular Cloning: a Laboratory Manual, Cold Spring Harbor Press, 1989).

As used herein, a "methylation sensitive restriction endonuclease" is a restriction endonuclease that includes CG as part of its recognition site and has altered activity when the C is methylated as compared to when the C is not methylated. Preferably, the methylation sensitive restriction endonuclease has inhibited activity when the C is methylated (e.g., SmaI). Specific non-limiting examples of a methylation sensitive restriction endonucleases include Sma I, BssHII, or HpaII. Such enzymes can be used alone or in combination. Other methylation sensitive restriction endonucleases will be known to those of skill in the art and include, but are not limited to SacII, EagI, and BstUI, for example. An "isoschizomer" of a methylation sensitive restriction endonuclease is a restriction endonuclease which recognizes the same recognition site as a methylation sensitive restriction endonuclease but which cleaves both methylated and unmethylated CGs. One of skill in the art can readily determine appropriate conditions for a restriction endonuclease to cleave a nucleic acid (see Sambrook et al., Molecular Cloning: a Laboratory Manual, Cold Spring

In another embodiment, detection of differential methylation is accomplished by contacting a nucleic acid sample suspected of comprising a CpG-containing nucleic acid with a methylation sensitive restriction endonuclease that cleaves only unmethylated CpG sites under conditions and for a time to allow cleavage of unmethylated nucleic acid. The sample is further contacted with an isoschizomer of the methylation sensitive restriction endonuclease, that cleaves both methylated and unmethylated CpG-sites, under conditions and for a time to allow cleavage of methylated nucleic acid. Oligonucleotides are added to the nucleic acid sample under conditions and for a time to allow ligation of the oligonucleotides to nucleic acid cleaved by the restriction endonuclease, and the digested nucleic acid is amplified by conventional methods such as PCR wherein primers complementary to the oligonucleotides are employed. Following identification, the methylated CpG-containing nucleic acid can be cloned, using method well known to one of skill in the art (see Sambrook et al., Molecular Cloning: a Laboratory Manual, Cold Spring Harbor Press, 1989).

As used herein, a "methylation sensitive restriction endonuclease" is a restriction endonuclease that includes CG as part of its recognition site and has altered activity when the C is methylated as compared to when the C is not methylated. Preferably, the methylation sensitive restriction endonuclease has inhibited activity when the C is methylated (e.g., SmaI). Specific non-limiting examples of a methylation sensitive restriction endonucleases include Sma I, BssHII, or HpaII. Such enzymes can be used alone or in combination. Other methylation sensitive restriction endonucleases will be known to those of skill in the art and include, but are not limited to SacII, EagI, and BstUI, for example. An "isoschizomer" of a methylation sensitive restriction endonuclease is a restriction endonuclease which recognizes the same recognition site as a methylation sensitive restriction endonuclease but which cleaves both methylated and unmethylated CGs. One of skill in the art can readily determine appropriate conditions for a restriction endonuclease to cleave a nucleic acid (see Sambrook et al., Molecular Cloning: a Laboratory Manual, Cold Spring

Harbor Press, 1989). Without being bound by theory, actively transcribed genes generally contain fewer methylated CGs than in other genes.

In one embodiment of the invention, a nucleic acid of interest is cleaved with a
5 methylation sensitive endonuclease. In one aspect, cleavage with the methylation
sensitive endonuclease creates a sufficient overhang on the nucleic acid of interest.
Following cleavage with the isoschizomer, the cleavage product can still have a
sufficient overhang. An "overhang" refers to nucleic acid having two strands wherein
the strands end in such a manner that a few bases of one strand are not base paired to
10 the other strand. A "sufficient overhang" refers to an overhang of sufficient length to
allow specific hybridization of an oligonucleotide of interest. In one embodiment, a
sufficient overhang is at least two bases in length. In another embodiment, the
sufficient overhang is four or more bases in length. An overhang of a specific
sequence on the nucleic acid of interest may be desired in order for an oligonucleotide
15 of interest to hybridize. In this case, the isoschizomer can be used to create the
overhang having the desired sequence on the nucleic acid of interest.

In another aspect of this embodiment, the cleavage with a methylation
sensitive endonuclease results in a reaction product of the nucleic acid of interest that
20 has a blunt end or an insufficient overhang. In this embodiment, an isoschizomer of
the methylation sensitive restriction endonuclease can create a sufficient overhang on
the nucleic acid of interest. "Blunt ends" refers to a flush ending of two stands, the
sense stand and the antisense strand, of a nucleic acid.

25 Once a sufficient overhang is created on the nucleic acid of interest, an
oligonucleotide is ligated to the nucleic acid cleaved of interest which has been
cleaved by the methylation specific restriction endonuclease. "Ligation" is the
attachment of two nucleic acid sequences by base pairing of substantially
complementary sequences and/or by the formation of covalent bonds between two
30 nucleic acid sequences. In one aspect of the present invention, an "oligonucleotide" is

a nucleic acid sequence of about 2 up to about 40 bases in length. It is presently preferred that the oligonucleotide is from about 15 to 35 bases in length.

In one embodiment, an adaptor is utilized to create DNA ends of desired sequence and overhang. An "adaptor" is a double-stranded nucleic acid sequence with one end that has a sufficient single-stranded overhang at one or both ends such that the adaptor can be ligated by base-pairing to a sufficient overhang on a nucleic acid of interest that has been cleaved by a methylation sensitive restriction enzyme or an isoschizomer of a methylation sensitive restriction enzyme. Adaptors can be obtained commercially, or two oligonucleotides can be utilized to form an adaptor. Thus, in one embodiment, two oligonucleotides are used to form an adaptor; these oligonucleotides are substantially complementary over their entire sequence except for the region(s) at the 5' and/or 3' ends that will form a single stranded overhang. The single stranded overhang is complementary to an overhang on the nucleic acid cleaved by a methylation sensitive restriction enzyme or an isoschizomer of a methylation sensitive restriction enzyme, such that the overhang on the nucleic acid of interest will base pair with the 3' or 5' single stranded end of the adaptor under appropriate conditions. The conditions will vary depending on the sequence composition (GC vs AT), the length, and the type of nucleic acid (see Sambrook et al., Molecular Cloning: a Laboratory Manual, 2nd Ed.; Cold Spring Harbor Laboratory Press, Plainview, NY, 1998).

Following the ligation of the oligonucleotide, the nucleic acid of interest is amplified using a primer complementary to the oligonucleotide. Specifically, the term "primer" as used herein refers to a sequence comprising two or more deoxyribonucleotides or ribonucleotides, preferably more than three, and more preferably more than eight, wherein the sequence is capable of initiating synthesis of a primer extension product, which is substantially complementary to a nucleic acid such as an adaptor or a ligated oligonucleotide. Environmental conditions conducive to synthesis include the presence of nucleoside triphosphates and an agent for polymerization,

such as DNA polymerase, and a suitable temperature and pH. The primer is preferably single stranded for maximum efficiency in amplification, but may be double stranded. If double stranded, the primer is first treated to separate its strands before being used to prepare extension products. In one embodiment, the primer is an oligodeoxyribo-nucleotide. The primer must be sufficiently long to prime the synthesis of extension products in the presence of the inducing agent for polymerization. The exact length of primer will depend on many factors, including temperature, buffer, and nucleotide composition. The oligonucleotide primer typically contains 12-20 or more nucleotides, although it may contain fewer nucleotides.

Primers of the invention are designed to be "substantially" complementary to each strand of the oligonucleotide to be amplified and include the appropriate G or C nucleotides as discussed above. This means that the primers must be sufficiently complementary to hybridize with their respective strands under conditions which allow the agent for polymerization to perform. In other words, the primers should have sufficient complementarity with a 5' and 3' oligonucleotide to hybridize therewith and permit amplification of CpG containing nucleic acid sequence.

Primers of the invention are employed in the amplification process which is an enzymatic chain reaction that produces exponential quantities of target locus relative to the number of reaction steps involved (e.g., polymerase chain reaction or PCR). Typically, one primer is complementary to the negative (-) strand of the locus and the other is complementary to the positive (+) strand. Annealing the primers to denatured nucleic acid followed by extension with an enzyme, such as the large fragment of DNA Polymerase I (Klenow) and nucleotides, results in newly synthesized + and - strands containing the target locus sequence. Because these newly synthesized sequences are also templates, repeated cycles of denaturing, primer annealing, and extension results in exponential production of the region (i.e., the target locus sequence) defined by the primer. The product of the chain reaction is a discrete

nucleic acid duplex with termini corresponding to the ends of the specific primers employed.

The oligonucleotide primers of the invention may be prepared using any suitable method, such as conventional phosphotriester and phosphodiester methods or automated embodiments thereof. In one such automated embodiment, diethylphosphoramidites are used as starting materials and may be synthesized as described by Beaucage, et al. (Tetrahedron Letters, 22:1859-1862, 1981). One method for synthesizing oligonucleotides on a modified solid support is described in U.S. Patent No. 4,458,066.

10

Where the CpG-containing nucleic acid sequence of interest contains two strands, it is necessary to separate the strands of the nucleic acid before it can be used as a template for the amplification process. Strand separation can be effected either as a separate step or simultaneously with the synthesis of the primer extension products. This strand separation can be accomplished using various suitable denaturing conditions, including physical, chemical, or enzymatic means, the word "denaturing" includes all such means. One physical method of separating nucleic acid strands involves heating the nucleic acid until it is denatured. Typical heat denaturation may involve temperatures ranging from about 80° to 105°C for times ranging from about 1 to 10 minutes. Strand separation may also be induced by an enzyme from the class of enzymes known as helicases or by the enzyme RecA, which has helicase activity, and in the presence of riboATP, is known to denature DNA. The reaction conditions suitable for strand separation of nucleic acids with helicases are described by Kuhn Hoffmann-Berling (CSH-Quantitative Biology, 43:63, 1978) and techniques for using RecA are reviewed in C. Radding (Ann. Rev. Genetics, 16:405-437, 1982).

20

When complementary strands of nucleic acid or acids are separated, regardless of whether the nucleic acid was originally double or single stranded, the separated strands are ready to be used as a template for the synthesis of additional nucleic acid strands. This synthesis is performed under conditions allowing hybridization of

30

primers to templates to occur. Generally synthesis occurs in a buffered aqueous solution, generally at a pH of about 7-9. Preferably, a molar excess (for genomic nucleic acid, usually about 108:1 primer:template) of the two oligonucleotide primers is added to the buffer containing the separated template strands. It is understood, however, that the amount of complementary strand may not be known if the process of the invention is used for diagnostic applications, so that the amount of primer relative to the amount of complementary strand cannot be determined with certainty. As a practical matter, however, the amount of primer added will generally be in molar excess over the amount of complementary strand (template) when the sequence to be amplified is contained in a mixture of complicated long-chain nucleic acid strands. a large molar excess is preferred to improve the efficiency of the process.

The deoxyribonucleoside triphosphates dATP, dCTP, dGTP, and dTTP are added to the synthesis mixture, either separately or together with the primers, in adequate amounts and the resulting solution is heated to about 90°-100°C from about 1 to 10 minutes, preferably from 1 to 4 minutes. After this heating period, the solution is allowed to cool to approximately room temperature, which is preferable for the primer hybridization. To the cooled mixture is added an appropriate agent for effecting the primer extension reaction (called herein "agent for polymerization"), and the reaction is allowed to occur under conditions known in the art. The agent for polymerization may also be added together with the other reagents if it is heat stable. This synthesis (or amplification) reaction may occur at room temperature up to a temperature above which the agent for polymerization no longer functions. Thus, for example, if DNA polymerase is used as the agent, the temperature is generally no greater than about 40°C. Most conveniently the reaction occurs at room temperature.

The agent for polymerization may be any compound or system which will function to accomplish the synthesis of primer extension products, including enzymes. Suitable enzymes for this purpose include, for example, E. coli DNA polymerase I, Klenow fragment of E. coli DNA polymerase I, T4 DNA polymerase, other available

DNA polymerases, polymerase muteins, reverse transcriptase, and other enzymes, including heat-stable enzymes (i.e., those enzymes which perform primer extension after being subjected to temperatures sufficiently elevated to cause denaturation such as Taq DNA polymerase, and the like). Suitable enzymes will facilitate combination
5 of the nucleotides in the proper manner to form the primer extension products which are complementary to each locus nucleic acid strand. Generally, the synthesis will be initiated at the 3' end of each primer and proceed in the 5' direction along the template strand, until synthesis terminates, producing molecules of different lengths. There may be agents for polymerization, however, which initiate synthesis at the 5' end and
10 proceed in the other direction, using the same process as described above.

Preferably, the method of amplifying is by PCR, as described herein and as is commonly used by those of ordinary skill in the art. However, alternative methods of amplification have been described and can also be employed. PCR techniques and
15 many variations of PCR are known. Basic PCR techniques are described by Saiki et al. (1988 Science 239:487-491) and by U.S. Pat. Nos. 4,683,195, 4,683,202 and 4,800,159, which are incorporated herein by reference.

The conditions generally required for PCR include temperature, salt, cation,
20 pH and related conditions needed for efficient copying of the master-cut fragment. PCR conditions include repeated cycles of heat denaturation (i.e. heating to at least about 95.degree. C.) and incubation at a temperature permitting primer: adaptor hybridization and copying of the master-cut DNA fragment by the amplification enzyme. Heat stable amplification enzymes like the pwo, *Thermus aquaticus* or
25 *Thermococcus litoralis* DNA polymerases are commercially available which eliminate the need to add enzyme after each denaturation cycle. The salt, cation, pH and related factors needed for enzymatic amplification activity are available from commercial manufacturers of amplification enzymes.

30 As provided herein an amplification enzyme is any enzyme which can be used for in vitro nucleic acid amplification, e.g. by the above-described procedures. Such

amplification enzymes include pwo, Escherichia coli DNA polymerase I, Klenow fragment of E. coli DNA polymerase I, T4 DNA polymerase, T7 DNA polymerase, Thermus aquaticus (Taq) DNA polymerase, Thermococcus litoralis DNA polymerase, SP6 RNA polymerase, T7 RNA polymerase, T3 RNA polymerase, T4 polynucleotide kinase, Avian Myeloblastosis Virus reverse transcriptase, Moloney Murine Leukemia Virus reverse transcriptase, T4 DNA ligase, E. coli DNA ligase or Q.beta. replicase. Preferred amplification enzymes are the pwo and Taq polymerases. The pwo enzyme is especially preferred because of its fidelity in replicating DNA.

10 Once amplified, the nucleic acid can be attached to a solid support, such as a membrane, and can be hybridized with any probe of interest, to detect any nucleic acid sequence. Several membranes are known to one of skill in the art for the adhesion of nucleic acid sequences. Specific non-limiting examples of these membranes include nitrocellulose (NITROPURE) or other membranes used in for
15 detection of gene expression such as polyvinylchloride, diazotized paper and other commercially available membranes such as GENESCREEN, ZETAPROBE (Biorad), and NYTRAN. Methods for attaching nucleic acids to these membranes are well known to one of skill in the art. Alternatively, screening can be done in a liquid phase.

20 In nucleic acid hybridization reactions, the conditions used to achieve a particular level of stringency will vary, depending on the nature of the nucleic acids being hybridized. For example, the length, degree of complementarity, nucleotide sequence composition (e.g., GC v. AT content), and nucleic acid type (e.g., RNA v.
25 DNA) of the hybridizing regions of the nucleic acids can be considered in selecting hybridization conditions. An additional consideration is whether one of the nucleic acids is immobilized, for example, on a filter.

 An example of progressively higher stringency conditions is as follows: 2 x
30 SSC/0.1% SDS at about room temperature (hybridization conditions); 0.2 x

SSC/0.1% SDS at about room temperature (low stringency conditions); 0.2 x SSC/0.1% SDS at about 42°C (moderate stringency conditions); and 0.1 x SSC at about 68°C (high stringency conditions). Washing can be carried out using only one of these conditions, e.g., high stringency conditions, or each of the conditions can be used, e.g., for 10-15 minutes each, in the order listed above, repeating any or all of the steps listed. However, as mentioned above, optimal conditions will vary, depending on the particular hybridization reaction involved, and can be determined empirically. In general, conditions of high stringency are used for the hybridization of the probe of interest.

10

The probe of interest can be detectably labeled, for example, with a radioisotope, a fluorescent compound, a bioluminescent compound, a chemiluminescent compound, a metal chelator, or an enzyme. Those of ordinary skill in the art will know of other suitable labels for binding to the probe, or will be able to ascertain such, using routine experimentation.

15

In one embodiment, representational difference analysis (RDA, see Lisitsyn et al., Science 259:946-951, 1993, herein incorporated by reference) can be performed on CpG-containing nucleic acid following MCA. MCA utilizes kinetic and subtractive enrichment to purify restriction endonuclease fragments present in one population of nucleic acid fragments but not in another. Thus, RDA enables the identification of small differences between the sequences of two nucleic acid populations. RDA uses nucleic acid from one population as a "tester" and nucleic acid from a second population as a "driver" in order to clone probes for single copy sequences present in (or absent from) one of the two populations. In one embodiment, nucleic acid from a "normal" individual or sample, not having a disorder such as a cell-proliferative disorder is used as a "driver," and nucleic acid from an "affected" individual or sample, having the disorder such as a cell proliferative disorder is used as a "tester." In one embodiment, the nucleic acid used as a "tester" is isolated from an individual having a cell proliferative disorder such as low grade astrocytoma,

30

anaplastic astrocytoma, glioblastoma, medulloblastoma, gastric cancer, colorectal cancer, colorectal adenoma, acute myelogenous leukemia, leukemia, lung cancer, renal cancer, breast cancer, prostate cancer, endometrial cancer and neuroblastoma. The nucleic acid used as a "driver" is thus normal astrocytes, normal glial cells, normal brain cells, normal gastric cells, normal colorectal cells, normal leukocytes, normal lung cells, normal kidney cells, normal breast cells, normal prostate cells, normal uterine cells, and normal neurons, respectively. In an additional embodiment, the nucleic acid used as a "driver" is isolated from an individual having a cell proliferative disorder such as low grade astrocytoma, anaplastic astrocytoma, glioblastoma, medulloblastoma, gastric cancer, colorectal cancer, colorectal adenoma, acute myelogenous leukemia, leukemia, lung cancer, renal cancer, breast cancer, prostate cancer, endometrial cancer and neuroblastoma. The nucleic acid used as a "tester" is thus normal astrocytes, normal glial cells, normal brain cells, normal gastric cells, normal colorectal cells, normal leukocytes, normal lung cells, normal kidney cells, normal breast cells, normal prostate cells, normal uterine cells, and normal neurons, respectively. One of skill in the art will readily be able to identify the "tester" nucleic acid useful with to identify methylated nucleic acid sequences in given "driver" population.

20 KITS

The materials for use in the assay of the invention are ideally suited for the preparation of a kit. Therefore, in accordance with another embodiment of the present invention, there is provided a kit it useful for the detection of a cellular proliferative disorder in a subject having or at risk for said cellular proliferative disorder.

25 Invention kits include a carrier means compartmentalized to receive a sample in close confinement therein, one or more containers comprising a first container containing a reagent which modifies unmethylated cytosine and a second container containing primers for amplification of a CpG-containing nucleic acid, wherein the primers distinguish between modified methylated and nonmethylated nucleic acid, and

30 optionally, a third container containing a methylation sensitive restriction

endonuclease. Primers contemplated for use in accordance with the invention include those set forth in SEQ ID NOs: 1-50.

Carrier means are suited for containing one or more container means such as
5 vials, tubes, and the like, each of the container means comprising one of the separate
elements to be used in the method. In view of the description provided herein of
invention methods, those of skill in the art can readily determine the apportionment of
the necessary reagents among the container means. For example, one of the
container means can comprise a container containing an oligonucleotide for ligation to
10 nucleic acid cleaved by a methylation sensitive restriction endonuclease. One or more
container means can also be included comprising a primer complementary to the
oligonucleotide. In addition, one or more container means can also be included which
comprise a methylation sensitive restriction endonuclease. One or more container
means can also be included containing an isoschizomer of said methylation sensitive
15 restriction enzyme.

In another embodiment, the kit may comprise a carrier means containing one
or more container means comprising a solid support, wherein the solid support has a
nucleic acid sequence of CACNA1G as described herein immobilized on the solid
20 support. In one embodiment, the solid support is a membrane. Several membranes
are known to one of skill in the art for the adhesion of nucleic acid sequences.
Specific non-limiting examples of these membranes include nitrocellulose (Nitropure)
or other membranes used in for detection of gene expression such as
polyvinylchloride, diazotized paper and other commercially available membranes
25 such as GENESCREEN, ZETAPROBE (Biorad), and NYTRAN. The CACNA1G
sequences immobilized on the solid support can then be hybridized to nucleic acid
sequences produced by performing the MCA procedure, bisulfite PCR or other
methylation detection methods on the nucleic acids of a sample of interest in order to
determine if the nucleic acid sequences contained in the sample are methylated.

The term "oligonucleotide primer" refers to a sequence of two or more deoxyribo-nucleotides or ribonucleotides, preferably at least eight, which sequence is capable of initiating synthesis of a primer extension product that is substantially complementary to a target nucleic acid strand. The oligonucleotide primer typically
5 contains fifteen to twenty-two or more nucleotides, although it may contain fewer nucleotides if the primer is complementary, so as to specifically allow the amplification of the specifically desired target nucleotide sequence.

The oligonucleotide primers for use in the invention may be prepared using
10 any suitable method, such as conventional phosphotriester and phosphodiester methods or automated embodiments thereof. In one such automated embodiment, diethyl-phos-phoramidites are used as starting materials and may be synthesized as described by Beaucage et al., Tetrahedron Letter, 22: 1859-1862 (1981). One method for synthesizing oligonucleotides on a modified solid support is described in U.S.
15 Patent No. 4,458,066. The exact length of primer will depend on many factors, including temperature, buffer, and nucleotide composition. The primer must prime the synthesis of extension products in the presence of the inducing agent for amplification.

20 Primers used according to the method of the invention are complementary to each strand of mutant nucleotide sequence to be amplified. The term "complementary" means that the primers must hybridize with their respective strands under conditions which allow the agent for polymerization to function. In other words, the primers that are complementary to the flanking sequences hybridize with
25 the flanking sequences and permit amplification of the nucleotide sequence. Preferably, the 3' terminus of the primer that is extended has perfectly base paired complementarity with the complementary flanking strand.

The term "flanks CpG-rich regions" refers to those DNA sequences on
30 chromosome that are upstream (5') or downstream (3') to the DNA sequence to be amplified. The sequence to be amplified is preferably a CpG-rich region in a gene or

regulatory region associated with a gene. For example, when the nucleotide sequence to be amplified is double stranded, a first sequence that is 5' to the nucleotide sequence and a second sequence that is 5' to the nucleotide sequence on the complementary strand flank the CpG-rich DNA sequence.

5

The nucleotide sequences that flank nucleotide repeats, i.e., the nucleotide sequences to which the oligonucleotide primers hybridize, may be selected from among the following nucleotide sequences: SEQ ID NO:1-50.

10 In general, the primers used according to the method of the invention embrace oligonucleotides of sufficient length and appropriate sequence which provide specific initiation of polymerization of a significant number of nucleic acid molecules containing the target nucleic acid under the conditions of stringency for the reaction utilizing the primers. In this manner, it is possible to selectively amplify the specific
15 target nucleic acid sequence containing the nucleic acid of interest. Oligonucleotide primers used according to the invention are employed in any amplification process that produces increased quantities of target nucleic acid.

The invention includes antibodies immunoreactive with CACNA1G
20 polypeptide or functional fragments thereof. Antibody which consists essentially of pooled monoclonal antibodies with different epitopic specificities, as well as distinct monoclonal antibody preparations are provided. Monoclonal antibodies are made from antigen containing fragments of the protein by methods well known to those skilled in the art (Kohler, *et al.*, *Nature*, 256:495, 1975). The term antibody as used in
25 this invention is meant to include intact molecules as well as fragments thereof, such as Fab and F(ab')₂, Fv and SCA fragments which are capable of binding an epitopic determinant on CACNA1G .

(1) An Fab fragment consists of a monovalent antigen-binding fragment of an
30 antibody molecule, and can be produced by digestion of a whole antibody molecule

with the enzyme papain, to yield a fragment consisting of an intact light chain and a portion of a heavy chain.

(2) An Fab' fragment of an antibody molecule can be obtained by treating a whole
5 antibody molecule with pepsin, followed by reduction, to yield a molecule consisting of an intact light chain and a portion of a heavy chain. Two Fab' fragments are obtained per antibody molecule treated in this manner.

(3) An (Fab')₂ fragment of an antibody can be obtained by treating a whole antibody
10 molecule with the enzyme pepsin, without subsequent reduction. A (Fab')₂ fragment is a dimer of two Fab' fragments, held together by two disulfide bonds.

(4) An Fv fragment is defined as a genetically engineered fragment containing the
15 variable region of a light chain and the variable region of a heavy chain expressed as two chains.

(5) A single chain antibody ("SCA") is a genetically engineered single chain molecule
20 containing the variable region of a light chain and the variable region of a heavy chain, linked by a suitable, flexible polypeptide linker.

As used in this invention, the term "epitope" refers to an antigenic determinant on an antigen, such as a CACNA1G polypeptide, to which the paratope of an antibody, such as an CACNA1G-specific antibody, binds. Antigenic determinants usually consist of chemically active surface groupings of molecules, such as amino
25 acids or sugar side chains, and can have specific three-dimensional structural characteristics, as well as specific charge characteristics.

As is mentioned above, antigens that can be used in producing CACNA1G-specific antibodies include CACNA1G polypeptides or CACNA1G polypeptide
30 fragments. The polypeptide or peptide used to immunize an animal can be obtained

by standard recombinant, chemical synthetic, or purification methods. As is well known in the art, in order to increase immunogenicity, an antigen can be conjugated to a carrier protein. Commonly used carriers include keyhole limpet hemocyanin (KLH), thyroglobulin, bovine serum albumin (BSA), and tetanus toxoid. The coupled peptide is then used to immunize the animal (e.g., a mouse, a rat, or a rabbit). In addition to such carriers, well known adjuvants can be administered with the antigen to facilitate induction of a strong immune response.

The invention also provides a method for detecting a cell proliferative disorder associated with CACNA1G in a subject, comprising contacting a target cellular component suspected of having a CACNA1G associated disorder, with a reagent which reacts with or binds to CACNA1G and detecting CACNA1G. The target cell component can be nucleic acid, such as DNA or RNA, or it can be protein. When the component is nucleic acid, the reagent is typically a nucleic acid probe or PCR primer. When the cell component is protein, the reagent is typically an antibody probe. The target cell component may be detected directly in situ or it may be isolated from other cell components by common methods known to those of skill in the art before contacting with a probe. (See for example, Maniatis, et al., Molecular Cloning, A Laboratory Manual, Cold Spring Harbor Laboratory, N.Y. 1989; Current Protocols in Molecular Biology, 1994, Ed. Ausubel, et al., Green Publ. Assoc. & Wiley Interscience.) Detection methods include Southern and Northern blot analyses, RNase protection, immunoassays and other detection assays that are known to those of skill in the art.

The probes can be detectably labeled, for example, with a radioisotope, a fluorescent compound, a bioluminescent compound, a chemiluminescent compound, a metal chelator, or an enzyme. Those of ordinary skill in the art will know of other suitable labels for binding to the probes or will be able to ascertain such, using routine experimentation.

Since the present invention shows that a decreased level of CACNA1G transcription is often the result of hypermethylation of the CACNA1G gene, it is often desirable to directly determine whether the CACNA1G gene is hypermethylated. In particular, the cytosine rich areas termed "CpG islands" which lie in the 5' regulatory regions of genes are normally unmethylated. The term "hypermethylation" includes any methylation of cytosine which is normally unmethylated in the CACNA1G gene sequence can be detected by restriction endonuclease treatment of CACNA1G polynucleotide (gene) and Southern blot analysis for example. Therefore, in a method of the invention, when the cellular component detected is DNA, restriction endonuclease analysis is preferable to detect hypermethylation of the CACNA1G gene. Any restriction endonuclease that includes CG as part of its recognition site and that is inhibited when the C is methylated, can be utilized. Methylation sensitive restriction endonucleases such as BssHII, MspI, NotI or HpaII, used alone or in combination are examples of such endonucleases. Other methylation sensitive restriction endonucleases will be known to those of skill in the art. In addition, PCR can be utilized to detect the methylation status of the CACNA1G gene. Oligonucleotide primers based on any coding sequence region in the CACNA1G sequence are useful for amplifying DNA by PCR. CACNA1G is described here for exemplary purposes. The other genes described herein as being

For purposes of the invention, an antibody or nucleic acid probe specific for CACNA1G may be used to detect the presence of CACNA1G polypeptide (using antibody) or polynucleotide (using nucleic acid probe) in biological fluids or tissues. Oligonucleotide primers based on any coding sequence region in the CACNA1G sequence are useful for amplifying DNA, for example by PCR. Any specimen containing a detectable amount of CACNA1G polynucleotide or CACNA1G polypeptide antigen can be used. Nucleic acid can also be analyzed by RNA in situ methods which are known to those of skill in the art. A preferred sample of this invention is tissue of heart, renal, brain, colon, breast, urogenital, uterine, hematopoietic, prostate, thymus, lung, testis, and ovarian. Preferably the subject is human.

Various disorders which are detectable by the method of the invention include astrocytoma, anaplastic astrocytoma, glioblastoma, medulloblastoma, colon cancer, lung cancer, renal cancer, leukemia, breast cancer, prostate cancer, endometrial cancer and neuroblastoma.

5

Monoclonal antibodies used in the method of the invention are suited for use, for example, in immunoassays in which they can be utilized in liquid phase or bound to a solid phase carrier. In addition, the monoclonal antibodies in these immunoassays can be detectably labeled in various ways. Examples of types of immunoassays which
10 can utilize monoclonal antibodies of the invention are competitive and non-competitive immunoassays in either a direct or indirect format. Examples of such immunoassays are the radioimmunoassay (RIA) and the sandwich (immunometric) assay. Detection of the antigens using the monoclonal antibodies of the invention can be done utilizing immunoassays which are run in either the forward, reverse, or
15 simultaneous modes, including immunohistochemical assays on physiological samples. Those of skill in the art will know, or can readily discern, other immunoassay formats without undue experimentation.

The term "immunometric assay" or "sandwich immunoassay", includes
20 simultaneous sandwich, forward sandwich and reverse sandwich immunoassays. These terms are well understood by those skilled in the art. Those of skill will also appreciate that antibodies according to the present invention will be useful in other variations and forms of assays which are presently known or which may be developed in the future. These are intended to be included within the scope of the present
25 invention.

Monoclonal antibodies can be bound to many different carriers and used to detect the presence of CACNA1G. Examples of well-known carriers include glass, polystyrene, polypropylene, polyethylene, dextran, nylon, amylases, natural and
30 modified celluloses, polyacrylamides, agaroses and magnetite. The nature of the

carrier can be either soluble or insoluble for purposes of the invention. Those skilled in the art will know of other suitable carriers for binding monoclonal antibodies, or will be able to ascertain such using routine experimentation.

5 In performing the assays it may be desirable to include certain "blockers" in the incubation medium (usually added with the labeled soluble antibody). The "blockers" are added to assure that non-specific proteins, proteases, or anti-heterophilic immunoglobulins to anti-CACNA1G immunoglobulins present in the experimental sample do not cross-link or destroy the antibodies on the solid phase
10 support, or the radiolabeled indicator antibody, to yield false positive or false negative results. The selection of "blockers" therefore may add substantially to the specificity of the assays described in the present invention.

 It has been found that a number of nonrelevant (i.e., nonspecific) antibodies of
15 the same class or subclass (isotype) as those used in the assays (e.g., IgG1, IgG2a, IgM, etc.) can be used as "blockers". The concentration of the "blockers" (normally 1-100 $\mu\text{g}/\mu\text{l}$) may be important, in order to maintain the proper sensitivity yet inhibit any unwanted interference by mutually occurring cross reactive proteins in the specimen.

20 In using a monoclonal antibody for the in vivo detection of antigen, the detectably labeled monoclonal antibody is given in a dose which is diagnostically effective. The term "diagnostically effective" means that the amount of detectably labeled monoclonal antibody is administered in sufficient quantity to enable detection
25 of the site having the CACNA1G antigen for which the monoclonal antibodies are specific. The concentration of detectably labeled monoclonal antibody which is administered should be sufficient such that the binding to those cells having CACNA1G is detectable compared to the background. Further, it is desirable that the detectably labeled monoclonal antibody be rapidly cleared from the circulatory system
30 in order to give the best target-to-background signal ratio.

As a rule, the dosage of detectably labeled monoclonal antibody for in vivo diagnosis will vary depending on such factors as age, sex, and extent of disease of the individual. The dosage of monoclonal antibody can vary from about 0.001 mg/m.sup.2 to about 500 mg/m.sup.2, preferably 0.1 mg/m.sup.2 to about 200 mg/m.sup.2, most preferably about 0.1 mg/m.sup.2 to about 10 mg/m.sup.2. Such dosages may vary, for example, depending on whether multiple injections are given, tumor burden, and other factors known to those of skill in the art.

For in vivo diagnostic imaging, the type of detection instrument available is a major factor in selecting a given radioisotope. The radioisotope chosen must have a type of decay which is detectable for a given type of instrument. Still another important factor in selecting a radioisotope for in vivo diagnosis is that the half-life of the radioisotope be long enough so that it is still detectable at the time of maximum uptake by the target, but short enough so that deleterious radiation with respect to the host is minimized. Ideally, a radioisotope used for in vivo imaging will lack a particle emission, but produce a large number of photons in the 140-250 keV range, which may be readily detected by conventional gamma cameras.

For in vivo diagnosis, radioisotopes may be bound to immunoglobulin either directly or indirectly by using an intermediate functional group. Intermediate functional groups which often are used to bind radioisotopes which exist as metallic ions to immunoglobulins are the bifunctional chelating agents such as diethylenetriaminepentaacetic acid (DTPA) and ethylenediaminetetraacetic acid (EDTA) and similar molecules. Typical examples of metallic ions which can be bound to the monoclonal antibodies of the invention are .sup.111 In, .sup.97 Ru, .sup.67 Ga, .sup.68 Ga, .sup.72 As, .sup.89 Zr, and .sup.201 Tl.

A monoclonal antibody useful in the method of the invention can also be labeled with a paramagnetic isotope for purposes of in vivo diagnosis, as in magnetic resonance imaging (MRI) or electron spin resonance (ESR). In general, any

conventional method for visualizing diagnostic imaging can be utilized. Usually gamma and positron emitting radioisotopes are used for camera imaging and paramagnetic isotopes for MRI. Elements which are particularly useful in such techniques include ^{157}Gd , ^{55}Mn , ^{162}Dy , ^{52}Cr , and ^{56}Fe .

5

The present invention also provides a method for treating a subject with a cell proliferative disorder associated with of CACNA1G comprising administering to a subject with the disorder a therapeutically effective amount of reagent which modulates CACNA1G expression. In brain, breast and renal cancer cells, for example, the CACNA1G nucleotide sequence is under-expressed as compared to expression in a normal cell, therefore, it is possible to design appropriate therapeutic or diagnostic techniques directed to this sequence. Thus, where a cell-proliferative disorder is associated with the expression of CACNA1G associated with malignancy, nucleic acid sequences that modulate CACNA1G expression at the transcriptional or translational level can be used. In cases when a cell proliferative disorder or abnormal cell phenotype is associated with the under expression of CACNA1G, for example, nucleic acid sequences encoding CACNA1G (sense) could be administered to the subject with the disorder.

20 The term "cell-proliferative disorder" denotes malignant as well as non-malignant cell populations which often appear to differ from the surrounding tissue both morphologically and genotypically. Such disorders may be associated, for example, with absence of expression of CACNA1G. Essentially, any disorder which is etiologically linked to expression of CACNA1G could be considered susceptible to treatment with a reagent of the invention which modulates CACNA1G expression.

The term "modulate" envisions the suppression of methylation of CACNA1G polynucleotide when CACNA1G is under-expressed. When a cell proliferative disorder is associated with CACNA1G expression, such methylation suppressive reagents as 5-azacytadine can be introduced to a cell. Alternatively, when a cell

30

proliferative disorder is associated with under-expression of CACNA1G polypeptide, a sense polynucleotide sequence (the DNA coding strand) encoding CACNA1G polypeptide, or 5' regulatory nucleotide sequences (i.e., promoter) of CACNA1G in operable linkage with CACNA1G polynucleotide can be introduced into the cell.

- 5 Demethylases known in the art could also be used to remove methylation.

The present invention also provides gene therapy for the treatment of cell proliferative disorders which are mediated by CACNA1G. Such therapy would achieve its therapeutic effect by introduction of the appropriate CACNA1G
10 polynucleotide which contains a CACNA1G structural gene (sense), into cells of subjects having the proliferative disorder. Delivery of sense CACNA1G polynucleotide constructs can be achieved using a recombinant expression vector such as a chimeric virus or a colloidal dispersion system.

15 The polynucleotide sequences used in the method of the invention may be the native, unmethylated sequence or, alternatively, may be a sequence in which a nonmethylatable analog is substituted within the sequence. Preferably, the analog is a nonmethylatable analog of cytidine, such as 5-azacytadine. Other analogs will be known to those of skill in the art. Alternatively, such nonmethylatable analogs could
20 be administered to a subject as drug therapy, alone or simultaneously with a sense structural gene for CACNA1G or sense promoter for CACNA1G operably linked to CACNA1G structural gene.

In another embodiment, a CACNA1G structural gene is operably linked to a
25 tissue specific heterologous promoter and used for gene therapy. For example, a CACNA1G gene can be ligated to prostate specific antigen (PSA)-prostate specific promoter for expression of CACNA1G in prostate tissue. Other tissue specific promoters will be known to those of skill in the art. Alternatively, the promoter for a tumor suppressor gene can be linked to the CACNA1G structural gene and used for
30 gene therapy.

Various viral vectors which can be utilized for gene therapy as taught herein include adenovirus, herpes virus, vaccinia, or, preferably, an RNA virus such as a retrovirus. Preferably, the retroviral vector is a derivative of a murine or avian retrovirus. Examples of retroviral vectors in which a single foreign gene can be inserted include, but are not limited to: Moloney murine leukemia virus (MoMuLV), Harvey murine sarcoma virus (HaMuSV), murine mammary tumor virus (MuMTV), and Rous Sarcoma Virus (RSV). Most preferably, a non-human primate retroviral vector is employed, such as the gibbon ape leukemia virus (GaLV), thereby providing a broader host range than murine vectors, for example.

A number of additional retroviral vectors can incorporate multiple genes. All of these vectors can transfer or incorporate a gene for a selectable marker so that transduced cells can be identified and generated. Retroviral vectors can be made target specific by inserting, for example, a polynucleotide encoding a sugar, a glycolipid, or a protein. Preferred targeting is accomplished by using an antibody to target the retroviral vector. Those of skill in the art will know of, or can readily ascertain without undue experimentation, specific polynucleotide sequences which can be inserted into the retroviral genome to allow target specific delivery of the retroviral vector containing the CACNA1G sense or antisense polynucleotide.

Since recombinant retroviruses are defective, they require assistance in order to produce infectious vector particles. This assistance can be provided, for example, by using helper cell lines that contain plasmids encoding all of the structural genes of the retrovirus under the control of regulatory sequences within the LTR. These plasmids are missing a nucleotide sequence which enables the packaging mechanism to recognize an RNA transcript for encapsidation. Helper cell lines which have deletions of the packaging signal include but are not limited to .PSI.2, PA317 and PA12, for example. These cell lines produce empty virions, since no genome is packaged. If a retroviral vector is introduced into such cells in which the packaging
